Recalling GADTs

GADTs allow us to express stronger invariants.

E.g., vectors without dependent types.

```
data Zero :: *  
data Succ :: * -> *  
  
data VecNat :: * -> * where  
  Nil :: VecNat Zero  
  Cons :: forall n. Nat -> VecNat n -> VecNat (Succ n)
```

Types are used as indices
(which means that we need to reason about equalities of types).

- Extend relational reasoning techniques to languages with GADTs, to be able to show representation independence results.
 - Calculus for GADTs: $F_{\omega\mu}^{=i}$.
 - Semantic models for $F_{\omega\mu}^{=i}$.
 - Unary model for semantic type safety.
 - Binary model for reasoning about contextual equivalences.

| | | |
|--------------|----------------|--|
| kinds | κ | $::= * \mid \kappa \Rightarrow \kappa$ |
| constructors | c | $::= \forall_{\kappa} \mid \exists_{\kappa} \mid \mu_{\kappa} \mid \rightarrow \mid \times \mid + \mid \text{unit} \mid \text{void}$ |
| constraints | χ | $::= \sigma \equiv_{\kappa} \tau$ |
| types | τ, σ | $::= \alpha \mid \lambda\alpha :: \kappa. \tau \mid \sigma \tau \mid c \mid \chi \rightarrow \tau \mid \chi \times \tau$ |

| | | |
|--------------|----------------|--|
| kinds | κ | $::= * \mid \kappa \Rightarrow \kappa$ |
| constructors | c | $::= \forall_{\kappa} \mid \exists_{\kappa} \mid \mu_{\kappa} \mid \rightarrow \mid \times \mid + \mid \text{unit} \mid \text{void}$ |
| constraints | χ | $::= \sigma \equiv_{\kappa} \tau$ |

| expressions | e | $::= \dots$ $\mid \text{abort } \bullet \mid v \bullet$ $\mid \text{let } (\bullet, x) = v \text{ in } e$ |

- Type constructors are built-in functions on types.
- Constraint types are ‘assert’s and ‘assume’s for type equalities.
- Constraints are ‘proof-irrelevant’.

Reasoning about equalities I

Provability

Computational rules (β, η for types), **injectivity**, congruence.

$$\frac{c :: (\kappa_i \Rightarrow)_i \kappa \quad \Delta \mid \Phi \Vdash c (\sigma_i)_i \equiv_{\kappa} c (\tau_i)_i}{(\Delta \mid \Phi \Vdash \sigma_i \equiv_{\kappa_i} \tau_i)_i}$$

$$\frac{\Delta \mid \Phi \Vdash \sigma_1 \times \tau_1 \equiv_* \sigma_2 \times \tau_2}{\Delta \mid \Phi \Vdash \tau_1 \equiv_* \tau_2}$$

Reasoning about equalities I

Provability

Computational rules (β, η for types), **injectivity**, congruence.

$$\frac{c :: (\kappa_i \Rightarrow)_i \kappa \quad \Delta \mid \Phi \Vdash c (\sigma_i)_i \equiv_{\kappa} c (\tau_i)_i}{(\Delta \mid \Phi \Vdash \sigma_i \equiv_{\kappa_i} \tau_i)_i}$$

$$\frac{\Delta \mid \Phi \Vdash \sigma_1 \times \tau_1 \equiv_* \sigma_2 \times \tau_2}{\Delta \mid \Phi \Vdash \tau_1 \equiv_* \tau_2}$$

Discriminability

For impossible case elimination it is enough to look at the **head** symbols.

$$\frac{c_1 \neq c_2 \quad (\Delta \vdash c_i \bar{\tau}_i :: \kappa)_{i \in \{1,2\}}}{\Delta \Vdash c_1 \bar{\tau}_1 \#_{\kappa} c_2 \bar{\tau}_2}$$

$$\frac{\Delta \vdash \tau_1 :: * \quad \Delta \vdash \tau_2 :: * \quad \Delta \vdash \sigma_1 :: * \quad \Delta \vdash \sigma_2 :: *}{\Delta \Vdash \tau_1 + \sigma_1 \#_* \tau_2 \times \sigma_2}$$

Elimination of impossible equalities.

$$\frac{\Delta \mid \Phi \Vdash \sigma_1 \equiv_{\kappa} \sigma_2 \quad \Delta \Vdash \sigma_1 \#_{\kappa} \sigma_2 \quad \Delta \vdash \tau :: *}{\Delta \mid \Phi \mid \Gamma \vdash \text{abort } \bullet : \tau}$$

$F_{\omega\mu}^i$ can represent GADTs

$\text{natvec} :: * \Rightarrow *$

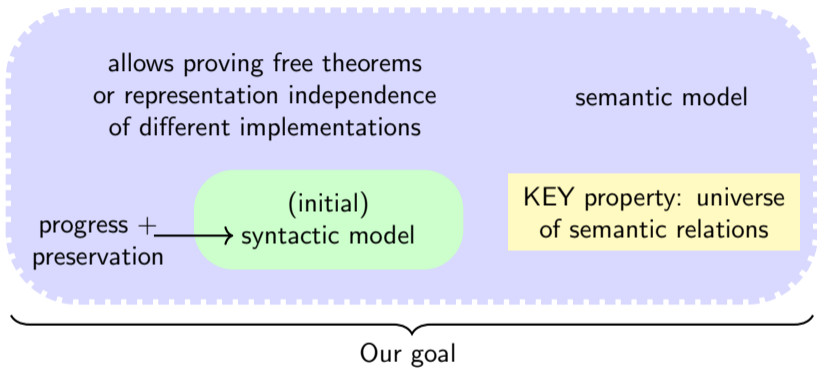

$\text{natvec} \triangleq$

$\mu\varphi :: * \Rightarrow *. \lambda\alpha :: *.$

$((\alpha \equiv_* \text{void}) \times \text{unit})$

$+ (\mathbb{N} \times \exists\beta :: *. (\alpha \equiv_* (\beta + \text{unit})) \times (\varphi \beta))$

- natvec is either **unit** (and has **void** as its index)
- or **not unit** (and the tail has a smaller index).

Naïve approach

- Types are interpreted as sets of values. Constraints are interpreted as equalities of these sets.
- We can't validate injectivity rules, e.g., consider this instance:

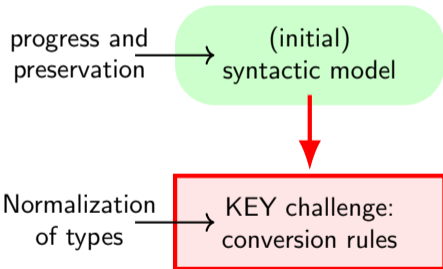

$$\frac{\Delta \mid \Phi \Vdash \text{void} \times \tau_1 \equiv_* \text{void} \times \tau_2}{\Delta \mid \Phi \Vdash \tau_1 \equiv_* \tau_2}$$

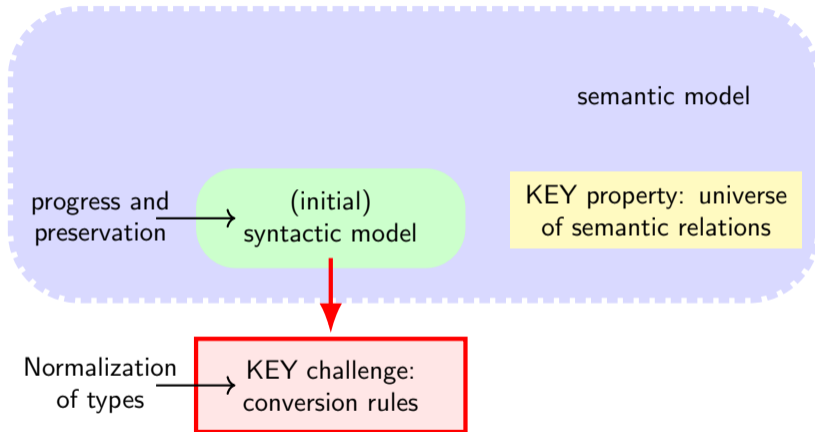

- If $\emptyset \times A = \emptyset \times B$, then it isn't necessarily true that $A = B$.

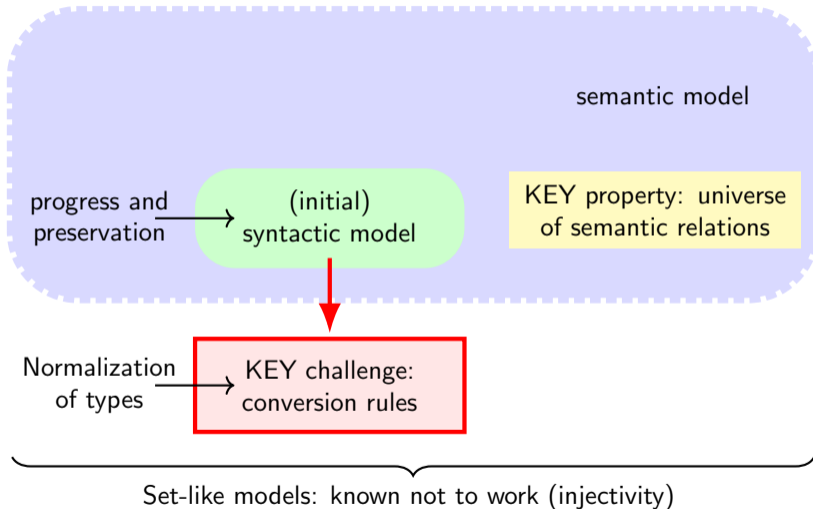

progress and
preservation

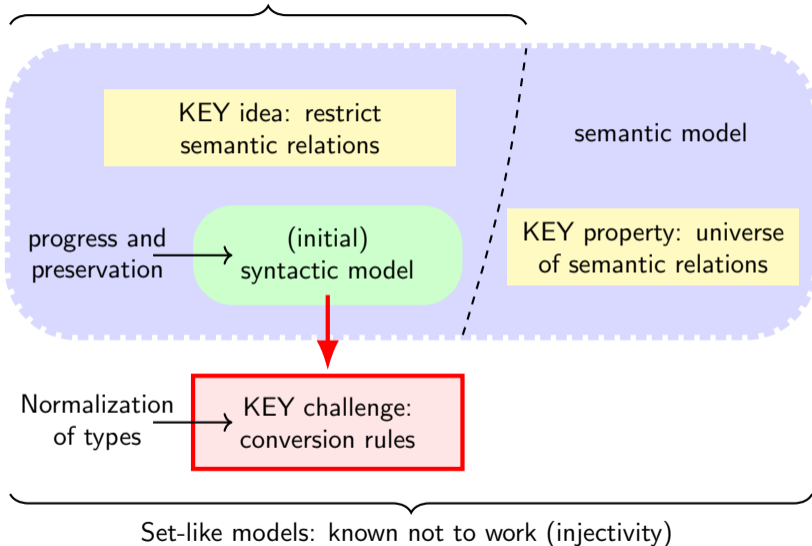

(initial)
syntactic model

Our model: validates injectivity rules + has a model with semantic relations

High-level view of model construction

Idea: two stages.

- The first stage helps to reason about equalities.
- The second stage is for sets of values.

- *Normal forms* of types.
- Normalization (*NbE*).
- Syntactic equality of normal forms validates reduction rules for types.

$(\Delta \vdash \tau \equiv_{\kappa} \sigma \text{ constr}) \text{ true} \stackrel{\Delta}{=} \text{normal form of } \tau = \text{normal form of } \sigma$

Second stage (unary model)

- We cannot use purely semantic predicates in \forall .
- Guarded recursion not only in case of recursive types, but also in \forall .
- We can interpret normal forms now, instead of arbitrary types.
- Syntactic equality of normal forms for constraints.

$$\mathcal{R}(\forall\alpha :: *. \tau)(v) \triangleq \exists e. v = \Lambda. e \wedge \forall \mu \in \text{Neu}_* \dots \rightarrow \triangleright_{\text{wp}}(\mathcal{R}(\text{eval}(\tau[\alpha \mapsto \mu])))(e)$$

$$\mathcal{R}(\chi \times \nu)(v) \triangleq \exists v'. v = \langle \bullet, v' \rangle \wedge \chi \text{ true} \wedge \mathcal{R}(\nu)(v')$$

Key observation

We can extend the syntax of normal forms at the base kind.

$$\frac{\varphi : X}{\varphi : \text{Neu}_*^\Delta}$$

Key observation

We can extend the syntax of normal forms at the base kind.

$$\frac{\varphi : X}{\varphi : \text{Neu}_*^\Delta}$$

If X is instantiated with relations on syntactic values, we can prove relational properties. This allows us to *combine* syntactic reasoning (via normal forms for types) and semantic reasoning.

Key observation

We can extend the syntax of normal forms at the base kind.

$$\frac{\varphi : X}{\varphi : \text{Neu}_*^\Delta}$$

If X is instantiated with relations on syntactic values, we can prove relational properties. This allows us to *combine* syntactic reasoning (via normal forms for types) and semantic reasoning.

Our model walks on a thin line in-between being too *syntactical* (no relational reasoning) and being too *semantical* (invalid):

- If the interpretation of equalities is too *semantical*, we cannot validate injectivity rules.
- If we use equalities of normal forms to interpret equalities, but use just syntactical normal forms, we cannot validate the conversion rules.

Contributions:

- Calculus for studies of GADTs.
- Novel approach to study semantics of feature-rich languages with syntactic constraints for types.
- Semantical models of a language that allows us to express GADTs:
 - Unary model that validates potential extensions for languages with GADTs.
 - Binary model that allows reasoning about representation independence.
- Coq mechanization.

and future:

- Extensions (general effects).
- Relational interpretation of \forall quantified at higher kinds.

$$\begin{aligned}
[[*]] &\triangleq \text{Neu}_* \\
[[\kappa_a \Rightarrow \kappa_r]] &\triangleq [[\kappa_a]] \Rightarrow [[\kappa_r]] \\
[[\Delta]] &\triangleq \prod_{\alpha :: \kappa \in \Delta} [[\kappa]]
\end{aligned}$$

$$\begin{aligned}
&\text{reify} : [[\kappa]] \Rightarrow \text{Nf}_\kappa \\
&\text{reflect} : \text{Neu}_\kappa \Rightarrow [[\kappa]] \\
&\text{eval} : \text{Ty}_\kappa^\Delta \rightarrow ([[\Delta]]) \Rightarrow [[\kappa]]
\end{aligned}$$

The head function is now total! (We can eliminate the impossible case.)

$\text{vhead} : \text{nenatvec} \rightarrow \mathbb{N}$

$\text{vhead } xs \triangleq$

let $(*, ys) = xs$ in

case unroll ys

| $\text{inj}_1(\bullet, w)$. abort \bullet

| $\text{inj}_2(y, -)$. y

Setup for the second stage

We used step-indexed logic for this version of the calculus.
Language features (e.g., state) might require additional gadgets.

$$\tau ::= T \mid Val \mid Expr \mid Prop \mid 1 \mid \tau + \tau \mid \tau \times \tau \mid \tau \rightarrow \tau$$

$$\begin{aligned} t, P ::= & x \mid v \mid e \mid F(t_1, \dots, t_n) \mid \\ & () \mid (t, t) \mid \pi_i t \mid \lambda x : \tau. t \mid t(t) \mid \\ & \text{inl } t \mid \text{inr } t \mid \text{case}(t, x.t, y.t) \mid \\ & \text{False} \mid \text{True} \mid t = t \mid P \Rightarrow P \mid P \wedge P \mid P \vee P \mid \\ & \exists x : \tau. P \mid \forall x : \tau. P \mid \triangleright P \mid \mu x : \tau. t \mid \dots \end{aligned}$$

$$\frac{\Gamma, x : \tau \vdash t : \tau \quad x \text{ is guarded in } t}{\Gamma \vdash \mu x : \tau. t : \tau}$$

$$\llbracket \Phi \rrbracket_\eta \text{ true} \triangleq \forall \varphi \in \Phi. \llbracket \varphi \rrbracket_\eta \text{ true}$$

$$\llbracket \Gamma \rrbracket_\eta \triangleq \{ \gamma \in \text{dom}(\Gamma) \rightarrow \text{Val} \mid \forall x \in \text{dom}(\Gamma). \mathcal{R}(\text{eval}(\Gamma(x))(\eta))(\gamma(x)) \}$$

$$\Delta \mid \Phi \mid \Gamma \models e : \tau \triangleq \forall \eta \in \llbracket \Delta \rrbracket(\cdot). \text{good}(\eta) \rightarrow \llbracket \Phi \rrbracket_\eta \text{ true} \rightarrow \forall \gamma \in \llbracket \Gamma \rrbracket_\eta \rightarrow \text{wp}(\mathcal{R}(\text{eval}(\tau)(\eta)))(e)$$

Injectivity and Cantor's paradox

Injectivity of some constructors implies false. It's a known fact, but can come up as a surprise.

For any injective constructor $c :: (* \Rightarrow *) \Rightarrow *$ and type $\alpha :: *$ it is possible to derive a value of type `void` in System F_{ω}^i .

For any injective constructor $c :: (* \Rightarrow *) \Rightarrow *$ and type $\alpha :: *$ it is possible to derive a value of type `void` in System F_{ω}^i .

- $\tau_c^{\text{loop}} \triangleq \exists \beta :: * \Rightarrow *. (c \beta \equiv_* \alpha) \times (\beta \alpha \rightarrow \text{void})$
- $v^{\text{loop}} \triangleq \lambda x. \text{let } (*, (\bullet, y)) = x \text{ in } y \text{ (pack } \langle \bullet, y \rangle)$
- $\vdash v^{\text{loop}} : \tau_c^{\text{loop}}[(c (\lambda \alpha :: *. \tau_c^{\text{loop}} \alpha))/\alpha] \rightarrow \text{void},$
- $\vdash v^{\text{loop}} \text{ (pack } \langle \bullet, v^{\text{loop}} \rangle) : \text{void}$

Lemma (Consistency)

A discriminable constraint is not provable in an empty context: in other words, $\emptyset \mid \emptyset \Vdash \tau_1 \equiv_{\kappa} \tau_2$ and $\emptyset \Vdash \tau_1 \not\equiv_{\kappa} \tau_2$ are contradictory.

- Consequence of the injectivity of reify.
- Allows to discharge impossible cases.

Lemma (Canonical form for arrows)

If v is a closed value of type τ and τ is provably equal to some arrow type in an empty context, then v is a lambda-abstraction with a well-typed body.

$$\begin{aligned} (\emptyset \mid \emptyset \Vdash \tau \equiv_* (\tau_1 \rightarrow \tau_2)) \wedge (\emptyset \mid \emptyset \mid \Gamma \vdash v : \tau) \\ \implies (\exists x e. v = \lambda x. e \wedge \emptyset \mid \emptyset \mid \Gamma, x : \tau_1 \vdash e : \tau_2) \end{aligned}$$

Orthogonal extensions

References and concurrency.

| | |
|--------------|---|
| constructors | $c ::= \dots \mid \text{ref}$ |
| references | $l ::= \mathbb{N}$ |
| values | $v ::= \dots \mid l$ |
| expressions | $e ::= \dots \mid \text{fork } e \mid \text{alloc } v \mid v := v \mid ! v$ |

The first stage stays the same, and the rest depends only on the logic used for defining \mathcal{R} .

The only requirements are that new effects should be expressed by type constructors, and that the ambient logic can express them.

Type-safe red-black trees

```
data Red
data Black
data Tree a where
  Tree :: Node Black n a -> Tree a

data Node t n a where
  Nil :: Node Black Zero a
  BlackNode :: NodeH t0 t1 n a -> Node Black (Succ n) a
  RedNode :: NodeH Black Black n a -> Node Red n a
data NodeH l r n a = NodeH (Node l n a) a (Node r n a)
```

Stronger type invariants.

Well-typed lambda terms

$$\text{Tm} :: * \Rightarrow *$$
$$\text{Tm} \triangleq$$
$$\mu\varphi :: * \Rightarrow *. \lambda\alpha :: *.$$
$$\alpha + (\exists\beta, \gamma :: *. (\alpha \equiv_* (\beta \rightarrow \gamma)) \times (\beta \rightarrow \varphi \gamma))$$
$$+ (\exists\beta :: *. \varphi (\beta \rightarrow \alpha) \times \varphi \beta)$$

Well-typed lambda terms

$\text{eval} : \forall \alpha :: *. \text{Tm } \alpha \rightarrow \alpha$

$\text{eval} \triangleq$

$\text{fix } \lambda f. \Lambda. \lambda x.$

$\text{case unroll } x$

$| \text{inj}_1 y. y$

$| \text{inj}_2 y. \text{case } y$

$| \text{inj}_1 (*, (*, (\bullet, g))). \lambda z. f * (g z)$

$| \text{inj}_2 (*, \langle g, x \rangle). (f * g) (f * x)$

Logical relation for denotations

For any two bigger related contexts and arguments in this extended contexts, results are related after extension.

$$\eta \mid \nu_1 \approx_* \nu_2 \triangleq \llbracket \nu_1 \rrbracket_\eta = \nu_2$$

$$\eta \mid \varphi_1 \approx_{\kappa_a \Rightarrow \kappa_r} \varphi_2 \triangleq \forall \Delta'_1, \Delta'_2, (\delta_1 : \text{hom}_{\mathcal{K}}(\Delta'_1, \Delta_1), \delta_2 : \text{hom}_{\mathcal{K}}(\Delta'_2, \Delta_2)), (\eta' : \llbracket \Delta'_1 \rrbracket^{\Delta'_2}), \mu_1, \mu_2. \\ (\delta_2^* \eta = \lambda x. \eta'(\delta_1(x))) \rightarrow (\eta' \mid \mu_1 \approx_{\kappa_a} \mu_2) \rightarrow (\eta' \mid \varphi_1(\delta_1, \mu_1) \approx_{\kappa_r} \varphi_2(\delta_2, \mu_2))$$

Lemma

If $\eta \mid \mu_1 \approx \mu_2$, then $\llbracket \text{reify}(\mu_1) \rrbracket_\eta = \mu_2$.

If $\eta \mid \eta_1 \approx \eta_2$, then $\eta \mid \llbracket \tau \rrbracket_{\eta_1} \approx \llbracket \tau \rrbracket_{\eta_2}$.

$$\iota \mid \nu \approx_{\kappa} \nu$$
